Introduction

This report deals with the activities conducted during the first and second seasons of the research project *Agricultura en terrazas en el cerro San Lucas, Valle de Teotihuacán*, (Terrace agriculture in Cerro San Lucas, Teotihuacan Valley), between December 2004 and January 2005, and from March 2nd to May 15th, 2005.

According to the work plan established in the project's proposal, during the first stage of fieldwork the surface survey was undertaken, and in the second stage the excavation of the chosen area.

In the first season we checked in the field the features observed through photo interpretation, we conducted the collection of material, the analysis of archaeological material on the surface, and did an airplane flyover to take aerial photos of Cerro San Lucas ([Figure 1](#)).

Photo 1. General view of the terrace.

Fieldwork conducted during this field season involved the survey of several fields showing archaeological materials and level changes on the surface. Once we knew the condition of the terraces showing the mentioned features, we chose a portion of a terrace for topographic survey and surface material collection. The chosen terrace belongs to Mr. Miguel Ortega Zúñig ([Photo 1](#)), who lives in the town of San Marcos, municipality of Otumba. According to Mr. Ortega, the terrace dimensions we see today in the hill reflect the leveling carried out with excavating machines on the hill slopes during the presidency of José López Portillo. During this period the *ejido* (communal property) lands in the region were distributed, so as to give the local peasants enough land for agriculture. In spite of the destruction caused by the heavy machinery within the ancient terraces (*tecorrales*), and on the possible walls of Prehispanic buildings, we were able to see slight level changes on the ground surface in some portions of the terrace which in some cases coincide with dark stains seen in the aerial photo, and in other cases with a differential growth of vegetation. In both cases the features are related with the existence of Prehispanic construction. In those areas where we see this micro topography there is a great amount of small stones, potsherds, and obsidian (boulders and flakes).

Photo 2. Vegetation and crops in the foothills and slopes of Cerro San Lucas.

Starting at the 2,500 m (above sea level) contour line toward the alluvial plain, the fields are cultivated mostly with barley, beans, and *nopal* cactus, while magueys, *pirul* trees and some nopales are used as boundary markers between terraces and fields. Above 2,500 m vegetation is mostly thorny and thornless underbrush ([Photo 2](#)).

During the second season we completed the topographic survey of the terrace, conducted the survey of our area of interest through three techniques, excavated the surveyed area, and took samples for chemical analysis, as well as pedological studies and soil micro morphology of the ground surface (thin sections), and for paleobotanical analysis (macro and micro remains). We established four level markers using a Global GPS, made a flyover with an aerostatic balloon to an approximate height of 100 m to obtain images of the excavated area, and finally the structure was consolidated and covered after the end of the field season.

2005 Season

First stage

Topographic survey

We established four level markers with approximate measurements above the *tepetate* (underground rock layer) that appears on the surface in several areas of the terrace. The markers were made of a round base of cement with a nail in the center. The point designated "A" is at E 530958.701 m, N 2179346.827 m, and at 2,482.025 m above sea level. From this point we could take in 118 other points, with which we could determine the shape of a portion of the chosen terrace.

The data base thus obtained was processed with the *Surfer* program (version 8), thus obtaining a configuration with a contour line interval of 10 cm, so as to record with greater detail the small rises seen on the ground relief ([Table 1](#)).

Surface material collection

The point from which the grid was established was located in the following coordinates: 19° 42' 55.8" (North latitude) and 98° 42' 28" (West longitude), with an orientation of 0° toward the north. From this point four squares measuring 15 by 15 m each were laid down to the east and south, divided up in squares of 1 by 1 m, to collect the archaeological material found on the surface in each square ([Photo 3](#)).

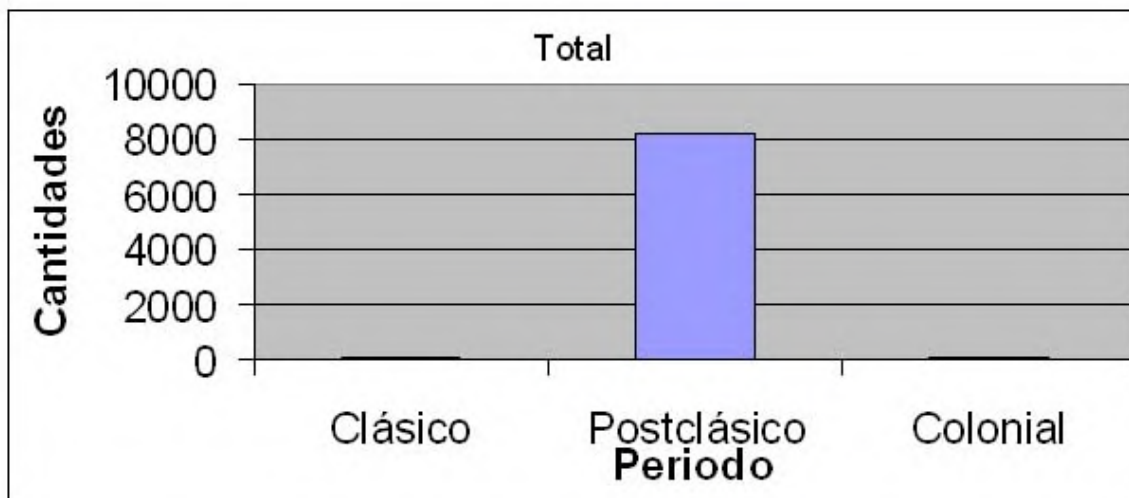

Photo 3. Setting up the grid for collecting surface material.

The collected material was washed and marked in the facilities of the Arizona State University's Teotihuacan Archaeological Center, which is on number 6, Aldama street, San Juan Teotihuacan, to be analyzed later. These materials were marked indicating bag number, followed by the corresponding square (1, E1S1). During three weeks the surface material was collected, ending up with a total amount of 1,720 bags.

In order to identify the ceramic material we followed the typologies established by Rattray (1966, 1973, 1979, and 2001), Parsons (1966), Müller (1978), Vega (1975), and Hodge and Minc (1991). The shape was the first criterion applied to the analysis of the ceramic material. The fragments found in each square were separated according to their shape: handle, bowl, pan, griddle (*comal*), figurine, jug, grater bowl (*molcajete*), pot (*olla*), incense burner, *salinera*, cup, and non-identified shapes. Most of the recovered sherds are smaller than 5 cm, and it was necessary to specify the part of the vessel to which the sherd belonged: rim, body, bottom or base, or appliqué. Once the groups were formed according to shape, the paste, surface finish, color, and decoration were the criteria that allowed us to recognize the types and therefore the phases or cultural periods.

Among the ground lithic artifacts we just distinguished between discard flakes, preforms, blades, scrapers, cores, boulders, and by color. Among the polished lithics we just distinguished general shapes such as *manos* for the *metate* (grindstone), mortar pestles (*manos de molcajete*) and polishers. Out of 1,720 bags we obtained a total of 9,113 items ([Table 4](#)), of which 8,237 sherds pertain to the Postclassic period, with pottery from the Azteca III phase as the dominant one; 98 sherds pertain to the Classic

period (1%), dominated by materials from the Tlamimilolpa phase, and finally 54 sherds (0.5%) from the Colonial period ([Table 2](#) and [Graph 1](#)).

Graph 1. Amounts of surface ceramic material, by period.

According to the data shown in [Table 3](#), we have a greater amount of bodies (6,963) of bowls, griddles, pans, incense burners, dishes, grater bowls, *salineras*, jars, jugs and cups, dominated by bowls, griddles, jars and jugs. The diagnostic shapes, although less abundant than the bodies, are well represented, basically in the form of bowls, griddles and dishes. We should point out the abundance of ceramic materials with cream slip, which according with the information provided by Charlton (personal communication 2005) may belong to a pottery variety from Texcoco.

Photo 4. Spindle whorls.

The presence of spindle whorls of two sizes suggests activities linked with the spinning of *ixtle* (maguey fiber), of a locally grown product, and of another one maybe brought from other regions ([Photo 4](#)).

Photo 5. Scrapers.

There is a striking abundance of small prismatic blades made with green obsidian as compared with the blades of gray obsidian, while the amount of flakes of gray obsidian is much more abundant than the green ones. This fact may suggest that the blades arrived as a finished product while the gray obsidian was worked locally, perhaps for making tools such as scrapers ([Photo 5](#)).

Aerial photography

Digital images (color and infrared) cover the entire Cerro San Lucas ([Photo 25](#) and [Photo 26](#)).

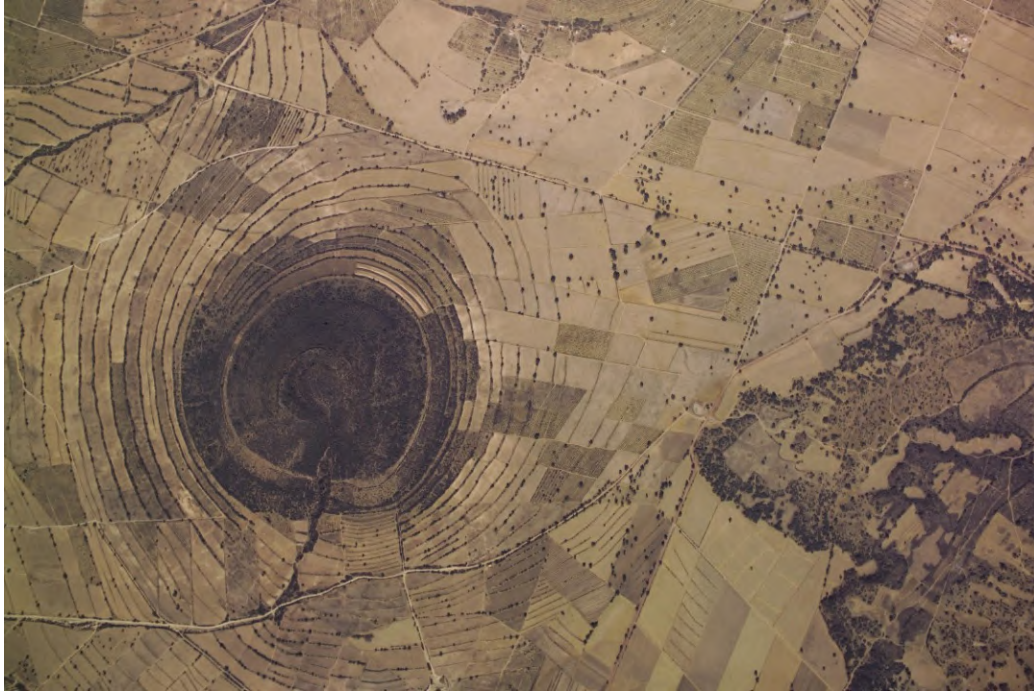

Photo 25. Aerial color photography of Cerro San Lucas.

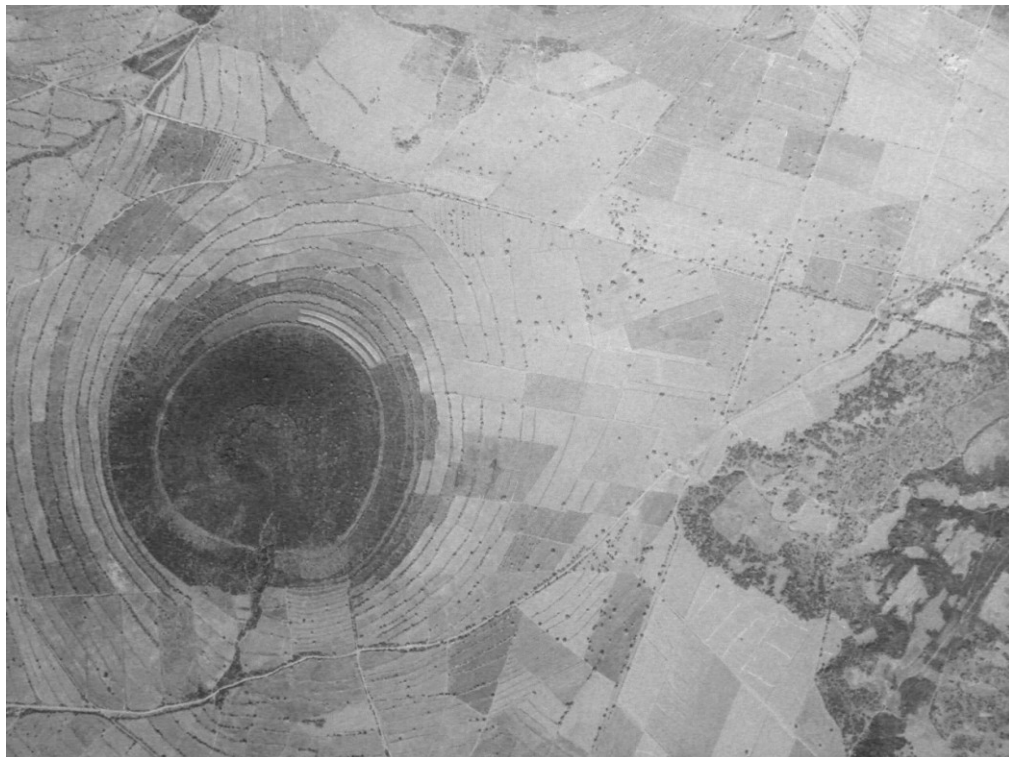

Photo 26. Aerial infrared photography of Cerro San Lucas.

Second Season

During the first week of March we set up the grid according to the reference points that had been established from the previous season. The area covered by the grid was 80 by 40 m, divided into squares of 1 x 1 m ([Photo 6](#)). During the second week of March we surveyed the remainder of the terrace to complement the work done during the previous season ([Figure 2](#)). We obtained 1,839 points which were added to the existing database ([Table 1](#)).

Photo 6. Setting up the grid.

On March 15th and 16th we conducted an archaeological survey of the study area previously analyzed through digital images, under the supervision of Dr. Luis Barba. In this survey we used three techniques to detect underlying structures, each one with different equipment and work teams.

Jorge Blancas, a geophysical engineer, located the three points that define the basic polygonal and the four grid corners set up for the survey, using a *Global GPS (Promark 2 model)* of submetric precision, with 12 channels and precision of cinematic mode (12 mm horizontally and 15 mm vertically), with an observation span of 20-30 seconds ([Photo 7](#)).

Archaeologist Agustín Ortiz measured the magnetic gradient using a GEOSCAN gradiometer with Fluxgate technology (model FM36) with a resolution of 0.1 nT and capacity for 16,000 readers in its memory ([Photo 8](#)).

Several students from Stanford University (Jeff Shragge, Brad Artman, Kyle Spikes and Laura Chiamonte) carried out a survey with a land-penetrating radar with a GSSI (Geophysical Survey System, Inc.) control unit (model SIR-2) and a monostatic antenna (transmitter-receiver) of 400 MHz with a depth of penetration of 3-6 m ([Photo 9](#)).

Photo 7. Measuring coordinates with Global GPS.

Photo 8. Prospecting with the gradiometer.

Photo 9. Prospecting with penetrating radar.

Photo 10. Geoelectric.

Finally, Dr. Gennaro Conte (post-doctoral fellow in the Geophysics Institute, UNAM) was in charge of the study of electrical resistivity ([Photo 10](#)), using a GEODE GXLV (A3000-E model) multi-electrode geo-electric survey equipment with 32 electrodes, with a capacity of 233 MHz.

On March 21st we started the excavations in the area, according to the results of the archaeological survey. The data were evident, so we decided to excavate the area where we would find a quadrangular structure ([Photo 11](#)).

Photo 11. Excavation of layer I.

We excavated extensively in a 14 by 14 m area, using both metric levels and natural strata. Upon finding the limits of the walls of a housing unit, we took aerial photos in order to have a general picture of the excavation. On May 6th we sampled the soil profiles in the excavation area, as well as in the upper terrace, for comparative purposes. This was undertaken by Dr. Elizabeth Solleiro and Dr. Sergey Sedov, both scholars from the Institute of Geology, UNAM ([Photo 12](#)).

Photo 12. Soil sampling.

Archaeological survey

Another grid was set up for the survey, perpendicular to the terrace, and oriented according to the one set up previously for surface artifact collection and excavation, 50° to the east in relation with the north-south axis of the first grid. The survey grid reached the following dimensions: 20 m wide by 80 m long, consisting of four modules of 20 x 20 m each.

The next step was to pinpoint the four corners of the grid set up for the survey, using the Global GPS, obtaining the following references:

Southwest corner, E 530960.049 m, N 2179350.915 m, with an elevation of 2479.275 m asl.

Northwest corner, E 530951.918 m, N 2179335.886 m, with an elevation of 2481.332 m asl.

Northeast corner, E 531001.625 m, N 2179368.786 m, with an elevation of 2481.715 m asl.

Southeast corner, E 531010.173 m, N 2179350.915 m, with an elevation of 2479.438 m asl.

Measuring the magnetic gradient was the first technique used in view of the relative ease of handling the equipment. The entire 20 x 80 m grid was covered by the gradiometer. After applying this technique the data were processed, discovering two features.

Between 20-40 m to the east and 8-20 m to the south there is an anomaly of quadrangular shape, whose northern boundary is not too clear. Another anomaly is found between 49-60 m to the east and 5-16 m to the south, showing a semicircular dipole-dipole pattern ([Figure 3](#)).

Once we could define the area where we would find the remains of some structure, the work with the radar and the geo-electric equipment focused only on the 20 and 60 meters of the grid.

Electric resistivity was measured on the ground using the dipole-dipole arrangement, made up of 32 electrodes put on the ground surface with three different distances (0.25 m, 0.50 m, 1 m). Twenty parallel profiles were made in an extension of 23.25 x 20 m ([Figure 4](#)). According with [Figure 4](#), red colors show high resistivity, and the limits of the structure are indicated by a purple color.

We went over the terrain with the ground-penetrating radar in an area of 40 x 20 m. The magnetic map revealed two rectangular structures ([Figure 5](#)); the one on the southwest showed an undefined magnetic pattern, with a great amount of surface material masking the dimensions of the walls, only the limits of the room can be seen. The

northeast structure shows a clearer magnetic pattern, clearly showing the wall dividing the two rooms as well as the perimeter walls, although the south wall's magnetic response is superimposed on the collapsed stones.

Based on the magnetic-gradient data we made a check-up with the georadar in the center of the structure to obtain information about the dimensions and depth of the magnetic patterns ([Figure 13](#)). The radargrams of lines 13 and 15 ([Figure 5](#)) showed superficial reflections of medium-to-great amplitude to a depth of 0.2-0.3 m, produced by the walls. We also recorded reflections produced by superficial stones that have no relation with lineal magnetic patterns. In the radargrams we can also see the fill material and remains of building material at a depth of 0-1.20 m. Between 1.20 and 1.30 m deep there is a horizontal reflection produced by contact with *tepetate* (underlying bedrock).

Toward the northeast we carried out the recording of magnetic gradient data in a sector that was not excavated. These data revealed a wide magnetic anomaly that can be interpreted as piled-up stones or a floor constructed with stones ([Figure 14](#)). Lines 32 and 34 were recorded with geo-radar over the great magnetic anomaly, in order to define the nature of the dipole ([Figure 15](#)). Radargrams show a 3.5-5 m long horizontal reflection in the dipole area, at a depth of 0.3 m. This anomaly was interpreted as the remains of a floor or a leveled surface; there is also a change in the texture and width of reflections at a depth of 1.3 m, indicating contact with the *tepetate*.

Lastly, we took 221 soil samples for chemical analysis at every 2 m, to determine the presence of carbonates (this analysis is currently underway).

Excavation

After the data obtained with the gradiometer, the geo-electric study and the radar showed the existence of a possible quadrangular structure between 21-37 m and 6-20 m, we decided to just excavate an area of 14 x 20 m.

Before starting the excavation we removed all the stones found on the surface. Although the first squares showed the presence of stones reddened by heating (observation made by Dr. Luis Barba), we thought that this information would not be of great use, since the passing of the radar and of more than 15 people over the area would modify its original distribution --although tractors have done the same thing years ago while plowing the land.

The excavation starting point was in the point of origin (0, 0) ([Figure 12](#)), advancing toward the north and south respectively with teams made up of two excavators and a siever. Layer I (or Ap horizon) was of variable depth and was removed from the area. This layer in general had a very loose consistency and a great amount of pottery fragments, a lesser amount of fragments of prismatic blades and discard flakes, and some stones reddened by heating, a few pieces of metal and a minimal amount of

modern glass. When removing this layer we thought it necessary to record the presence of reddened stones, which concentrated on the northeastern quadrant.

Photo 13. Traces showing the presence of the structure's east wall.

Layer II was more compact, no doubt because of the tractor passing over it during cultivation. On this layer's surface we distinguished small marks, whose orientation coincided with that of the grooves. We assume they are the marks left by the tractor's blades when the earth is moist. One of the longer marks was seen to the east of the eastern wall, somehow indicating the difference between the presence of underlying rocks belonging to the wall and the absence of them outside the wall ([Photo 13](#)). In layer II, at an average depth of 25 cm below the surface, we began finding the stones that had formed the east and north walls, which had three and four courses of stone, while the west and south walls had two and one courses respectively, at a greater depth. We can assume that layer II is the matrix containing the stones of the structure's walls.

It is important to point out that, although this layer presented a greater amount of cultural material, mainly Prehispanic ceramics and obsidian, this material was fragmented and mixed up with recent cultural material, such as coins from last century, shotgun casings and modern glass. We also found a great amount of *tezontle* (volcanic rock) spheres, *manos* (grindstones) ([Photo 14](#)), *metates* (querns) ([Photo 15](#)), *tejolotes* (some of them complete), and a great amount of collapsed stone. The presence of very small fragments of charcoal distributed throughout the layer is an important feature of layer II.

Photo 14. Grinding piece for metate.

Photo 15. Corner of metate.

Layer II was the one showing the greater amount of material, and we were able to recover some items in situ. In the E6 N10 square, below the stones that once were part of the wall, but that were totally removed by the tractor, there was a whole jar neck ([Photo 16](#)) while the rest of the body was distributed among squares E6 N10 and E7 N10. The earth from inside the neck and around it was collected for paleobotanical analysis.

Photo 16. Semicomplete jar, E6N10 square.

In the E4 N1 square, under a fragment of tamped earth, we found a group of three blades, two broken and one complete ([Photo 17](#)). They were collected together with samples of the matrix that had contained them, and some bones (apparently bird).

In the E6 N8 square we found a hearth formed by a polished stone perpendicular to the northern wall, located 16 cm south of the south face of the north wall, measuring 68 cm long by 10.5 cm wide in its southern end and 8 cm in the northern end ([Photo 18](#)). To the east side of the polished stone there is a fragment of burnt tamped earth, followed by several stones forming a rectangle measuring 68 cm wide by the length of the aforementioned stone. This cluster of rocks was covered by abundant ash, which was sieved, identifying a carbonized seed belonging to the Fabaceae family (*Phaseolus* sp.). We took samples both of the tamped earth and the ash for further analysis.

Photo 17. Complete blade under tamped earth.

Photo 18. Hearth.

Layer III was a hard crust of degraded *tepetate* with a highly irregular relief. The structure walls were erected on top of layer III, which was overlying the *tepetate* (layer IV) ([Figure 6](#)). In some places, mainly to the east of the eastern wall, we could see a marked depression which apparently was filled up with clay-like earth, of a very hard consistency and mixed up with potsherds, ash and charcoal, very similar in consistency and color to the mud used by the builders of this unit to cement the wall stones.

Upon reaching the *tepetate* the walls were cleaned up, exposing as far as possible the superficial stones. The cultural material recovered from the mortar was put in separate bags.

Description of the stratigraphic profiles

Profile 1 is located on the upper terrace at 19° 42' 42.8" north latitude, 98° 42' 6.9" west longitude, with an elevation of 2491 m asl. North wall ([Photo 19](#)).

Photo 19. Profile 1.

Horizon A (0-5 cm) is very little developed, with granular structure, porous, and showing a high density of roots, very fine to medium. The lower boundary is undulating, has a 2 mm- thick crust of lighter color than the surface (gray brown). AB horizon (5-21 cm) has more structure, with subangular blocks (8 cm) that break up into smaller subangular blocks. The main difference with the upper horizon has to do with structure, porosity, hardness and a lesser amount of roots than the former one.

BC horizon (21-43 cm) consists of big angular blocks, up to 6 cm. Its color is light brown and there is an increase in the amount of stones. It is very porous and shows features of soil creation.

C1 horizon (43-90 cm) original material.

C2 horizon (90-150 cm) original material.

E9 N13 Square, North Wall

Layer I (0-5/12 cm), light brown clay-sand which has lost its structure. Variable thickness, with a lower boundary up to 12 cm deep. This is a very loose earth with medium-sized (2.7 cm on the greatest axis) and small (0.9 cm on the greatest axis) angular and subangular stones, some of them reddened by fire.

Layer II (5/12-20 cm), light brown clay-sandy earth showing a harder consistency than layer I, maybe due to the passing of the machinery used to cultivate the field. It has a prismatic structure with big (11.1 x 8 cm), medium (5.6 x 5.4 cm) and small (1.2 x 1 cm), stones, as well as gravels. There are some concentrations of harder, grayish earth.

Layer III (20-30 cm) has sandier earth than the previous layer, dark brown, granular structure with charcoal fragments and a greater amount of gravels than layer II, as well as big and medium-sized stones.

Layer IV (30-46 cm) is a crust of light-brown degraded *tepetate*, with prismatic structure and hard consistency which is fractured into small subangular prisms. This layer has no cultural material.

Layer V (46 cm - ↓), brown-yellow *tepetate* of very hard consistency.

E5 S3 Square, East Wall

Layer I (0-15 cm), earth with a clay-sandy texture, angular and subangular structure, gray color, showing calcium carbonates.

Layer II (15-37 cm), clay-sandy earth with a more developed structure, with stable angular blocks with a more wrinkly surface. Blocks are medium-sized and break up into small granules, showing calcium carbonates.

Layer III (37-42/62 cm), clay-sandy earth of lighter color (grayish brown). Its structure consists of angular, thick blocks which produce no granules on fracture. This layer shows calcium carbonates in the canals left by the roots.

Layer IV (62- ↓), crust of degraded *tepetate*, dark brown color, of prismatic structure and hard consistency that breaks into small subangular prisms and shows no cultural material ([Photo 20](#)).

Photo 20. Profile 3, E5S3.

W4 S5 Square, South Wall

Layer I (0-5/12 cm), clay-sandy earth, showing variations in depth due to agricultural work on the surface. This a loose, porous earth, with abundant roots showing a structure of small, granular subangular blocks.

Layer II (5/12-31 cm), clay-sandy earth with bigger, angular and subangular blocks, rocky (30-40% rocks).

Layer III (31-47 cm), mud-clay earth with a poorly-developed structure, in subangular blocks. Rich in muddy and anthropic materials.

Layer IV (47 cm- ↓), crust of degraded, dark-brown *tepetate* with a prismatic structure of hard consistency which breaks into small subangular prisms and shows no cultural material ([Photo 21](#)).

Photo 21. Profile 4, W4S5.

Architecture

According to the preliminary data derived from the surface survey during the first stage of fieldwork, we thought it would be possible to find the remains of ancient constructions, specifically domestic units of the Aztec period. The ceramic material collected from the surface clearly shows its domestic character, consisting mainly of bowls, jars, jugs and griddles, as well as grindstones (*manos*) and fragments of quern (*metates*) bodies, linked with grinding activities inside the house. It is important to point out the presence of potsherds with lime adhering to the inside, the outside or both, as well as sherds with a cream slip, which may be linked with the production and handling of lime.

Survey revealed concrete data, such as the depth, location, shape, and dimensions of the underlying structure. We confirmed the existence of the remains of a quadrangular structure at 25 cm on average below the surface.

Undoubtedly, excavation would confirm the inferences from photo interpretation, surface survey, and archaeological prospecting (gradiometer and geoelectrical).

Extensive excavation was carried out in an area of 14 x 20 m. Although we were aware of the fact that the passing of the tractor over the terrace for many years might have destroyed a great deal of the structure, it was possible to find the remains of a housing unit, which we assume was occupied during the Late Aztec and Early Colonial periods ([Photo 22](#)).

Photo 22. Aerial view of the excavation.

This is a house bordered on four sides by walls with the following measurements: the north wall is 7.52 m long and is of varying width: 39 cm in the eastern end, 40 cm in the middle, and 38 cm in the western end. Four rows of stone were preserved, starting right from the crust of degraded *tepetate*. The stones were united by a dark-brown mud of hard consistency with cultural material, specifically ceramics and obsidian ([Figure 7](#)).

The south wall is 7.25 m long, with a width of 35 cm in its eastern end, 28 cm in its middle and 36 cm in its western end. This wall was found virtually destroyed, with just one row of stones preserved in a discontinuous pattern, placed directly over layer IV or *tepetate* crust ([Figure 8](#)).

The east wall is 13.36 m long, 33 cm wide on its north end, 32 cm wide on its middle, and 39 cm on its south end ([Figure 9](#)). Two or three rows of stone were preserved from this wall, cemented with a dark-brown mud of hard consistency mixed up with cultural material (ceramics and obsidian).

The west wall is 12.68 m long, toward the north end it is 38 cm wide, 39 cm wide in the middle, and 40 cm wide in its south end ([Figure 10](#)). Of this wall two courses of stone remain, placed directly on layer IV (the *tepetate* crust), cemented with dark-brown mud of hard consistency and mixed up with cultural material (ceramics and obsidian).

This housing unit had an average extension of 13 by 7 m, and had three rooms ([Figure 11](#)); one on the northwest corner which I assume was bordered by inner walls, of which a few stones remain (as can be seen in the drawing, [Figure 11](#)). Due to the presence of a hearth in this room, it is thought to be the kitchen area. It is important to mention that no remains of tamped earth were found, except for a fragment in the hearth.

Room 2 is L-shaped, bordered on the north and east by the interior walls that separate it from the kitchen, on the east by the east wall, and on the south by an interior wall showing a step, which leads me to believe that rooms 1 and 2 were on a higher level from the third room. A fragment of tamped earth was preserved in this room, stuck to the stones of the west wall (in the E1-E2, N6 squares). This tamped earth showed a whitish hue, so we applied hydrochloric acid, to which it reacted. Under the tamped earth was a layer of clay-like earth, brown and of hard consistency, which in general had very little cultural material. Under this layer was found the *tepetate* crust (layer IV).

Room number three is on the south side of the structure, bordered on the east, south, and north by the walls of the structure and on the north by the interior wall that separates rooms 2 and 3. In this room we found two fragments of tamped earth in different levels, with a difference of 10 cm between one and the other. One tamped earth fragment was found in square E4, N1, and the other one 10 cm below, in square E3, S4.

Consolidation and excavation closure

After drawing the ground plan and profiles of the structure walls, we carried on with the consolidation ([Photo 23](#)). Considering that the builders of this house used mud to cement the stones, we decided to use a mixture of earth from the excavation and sand, instead of lime, sand, and cement in the usual proportions. After removing the covering, the walls were moistened, the mortar was applied between the clean stones and we finished by cementing the walls (indicating the restored areas). Once the consolidation was finished we let it dry for one day and finally the structure was covered with the earth obtained during the excavation ([Photo 24](#)).

Photo 23. Consolidation of the walls.

Photo 24. Excavation closure.

Conclusions

In spite of the evident decay in the region due to several causes, among them the yearly use of the tractor during the last 15 years, which almost totally razed the walls of the observed housing unit, as well as the perturbation that removed the few architectonic features in the zone, we have been able to recover the data presented in this report.

The design of research strategies involving the use of techniques derived from the geosciences allowed first to optimize resources and time, and second to recover concrete and detailed information in those areas destined for total destruction.

We expect that the analyses currently under way (analyses of archaeological materials from excavation, identification of carbonized seeds, pollen, phytoliths, chemical and physical analyses of soils, soil chemistry, soil micro-morphology and C-14 dating) will give us the necessary information to establish the chronology, settlement type, and domestic economic activities in the rural village which was established in the slopes of the Cerro San Lucas, as mentioned by Evans (1988, 1991).

Activities that remain to be performed:

Excavation of the round anomaly;
Analysis of the excavated archaeological materials (ceramics, flaked lithics, polished lithics and bone);
Analysis of macro remains;
Analysis of pollen and phytoliths;
Chemical analysis and analysis of residues on soils and pottery;
Soil micro morphology;
Physical and chemical soil analysis;
Results of carbon samples.

Proposal for the project's second excavation season

In the project submitted last year (Pérez 2004) we emphasized the importance of finding indicators linked with agricultural activities in the terraces built for housing and for cultivation. The information recovered from both terraces will enable us to propose a possible relationship on two functional levels: between activities carried out inside the domestic unit and the *calmil* (adjoining garden), as well as between the domestic unit and the agricultural terrace.

According to the work plan outlined in the project proposal, during the first stage of work we carried out the surface reconnaissance, and the excavation of the selected area in the second stage.

In the first season we ground-checked the features observed through photo interpretation, collected material, analyzed the archaeological material collected from the surface, and did a fly-over to take aerial photos of Cerro San Lucas.

In the second season we complemented the topographic survey of the terrace, carried out the prospecting of the area of interest through three techniques, excavated the prospected area, took samples for chemical analysis of the surface, for pedological analysis and soil micromorphology (thin sections), as well as paleobotanical analysis (macro and micro remains) (all these analysis are currently underway). We established four (arbitrary) level markers through a Global GPS, carried out a fly-over on an

aerostatic balloon to an approximate altitude of 100 m to obtain images of the excavated area, and lastly consolidated the structure and covered it up at the end of the season.

According to the information obtained through the gradiometer, we have two relevant anomalies, one of quadrangular shape between 20-40 m to the east and 8-20 m to the south ([Figure 3](#) and [Figure 5](#) in the enclosed report), which corresponds with the structure we excavated in March-May, and a circular one at 49-60 m to the east and 5-16 m to the south, showing a dipole-dipole semi circular pattern. The latter feature was not excavated due to lack of funds and time ([Figure 3](#) and [Figure 5](#) in the enclosed report).

Toward the northeast we carried out the survey of magnetic gradient data in the unexcavated sector. These data revealed a magnetic anomaly of great amplitude, which may be interpreted as a great amount of piled-up stones, or else a floor constructed with stones ([Figure 14](#) in the enclosed report). Over the great magnetic anomaly we set up lines 32 and 34 with the georadar, to determine the nature of the dipole ([Figure 15](#) in the enclosed report). The radargrams show in the dipole zone a horizontal reflection 3.5-5 m long, at a depth of 0.3 m. This anomaly was interpreted as the remains of a floor or a leveled surface. We also saw a change of texture and amplitude of reflections at a depth of 1.3 m, indicating contact with the *tepetate*. The presence on the surface of a great amount of heat-reddened stones and the semi circular anomaly allow us to assume with all certainty that we are dealing with an oven.

According to Evans (1988, 1991, 1996), the rural village settled on the slopes of Cerro San Lucas has enough material evidence to assume an economic specialization linked mainly with maguey cultivation and processing. Of the nine residences excavated by Evans (1988), seven showed a considerable amount of tools linked with procuring both fibers and *pulque*, such as scrapers, spindle whorls, and jars.

If we were to excavate this oven, we would get information about the activities performed by the people who lived in this unit, beyond the agricultural realm. We will be able to recover information about the type of oven, its use, dimensions, and building materials; all this linked with the economic specialization achieved by this settlement during the Late Postclassic in the Teotihuacan Valley.

We propose a second excavation season of nine weeks, starting from February 1st 2006, with the following activities: During February 1-17, we intend to survey other similar areas detected in the aerial photo given to us by biologist Armando Peralta of the Photogrametry and Remote Sensing Lab of the Institute of Geography (UNAM). We will also be using the gradiometer, the radar and the geoelectrical detector, with the participation of the prospecting team of the Institute of Anthropological Research (UNAM), under the direction of Dr. Luis Barba and Dr. Genaro Conte (postdoctoral fellow in Mexico).

During February 20-28 we will investigate the limits of the geomorphological units analyzed in the lab under the supervision of Dr. Jorge López Blanco, of the Physical Geography Department of the Institute of Geography (UNAM). During March 1-31 we will excavate the circular feature detected by the gradiometer and the georadar, as well as sampling the excavated area for complementary analyses (macro remains, phytoliths, and chemical analysis). We will correct the level markers according to the data of the geodesic points provided by INEGI, sample the soils by geomorphological unit, and perform the pedological analysis, analyze the macro remains, pollen, and phytoliths, as well as taking *tepetate* samples for thin sections.
